How to use it

7

Currently implemented

Sysprop as api is a new feature on Android 10.0. As the literal meaning, In Sysprop as api rule, all access to property must by using the api, so why we need sysprop as api, What's wrong with the previous access method?

- Interfaces aren't explicitly defined
  - Hard to know exact dependencies
- Stability isn't guaranteed
  - Can be deleted/alterd anytime
- No schema at code level
  - Keys are random magic strings (OH NO)
  - Values are stored as strings, regardless of type (Please..)

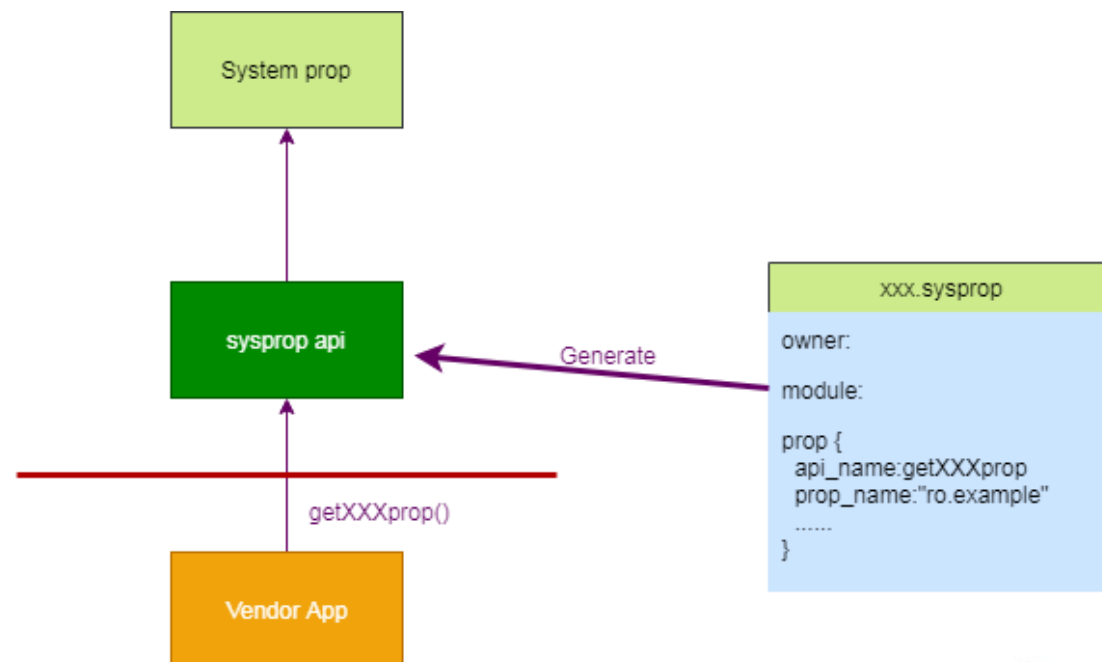

So, sysprop as api is coming.

Google defines the Sysprop Description file (.sysprop). According to google suggestion, every prop that needs to be accessed across partitions needs to be implemented in this way.

Currently, this new feature on Android 10.0 does not enforce module to implement it.

## Sysprop as api architecture

- Explicitly defines properties
  - Concrete and Typed API across partitions
    - methods for Java / functions for C++
- Supports API Stabilization
  - Build will break if changed
- Gives consistency between C++ and Java world

## New access method(1/2)

- Java

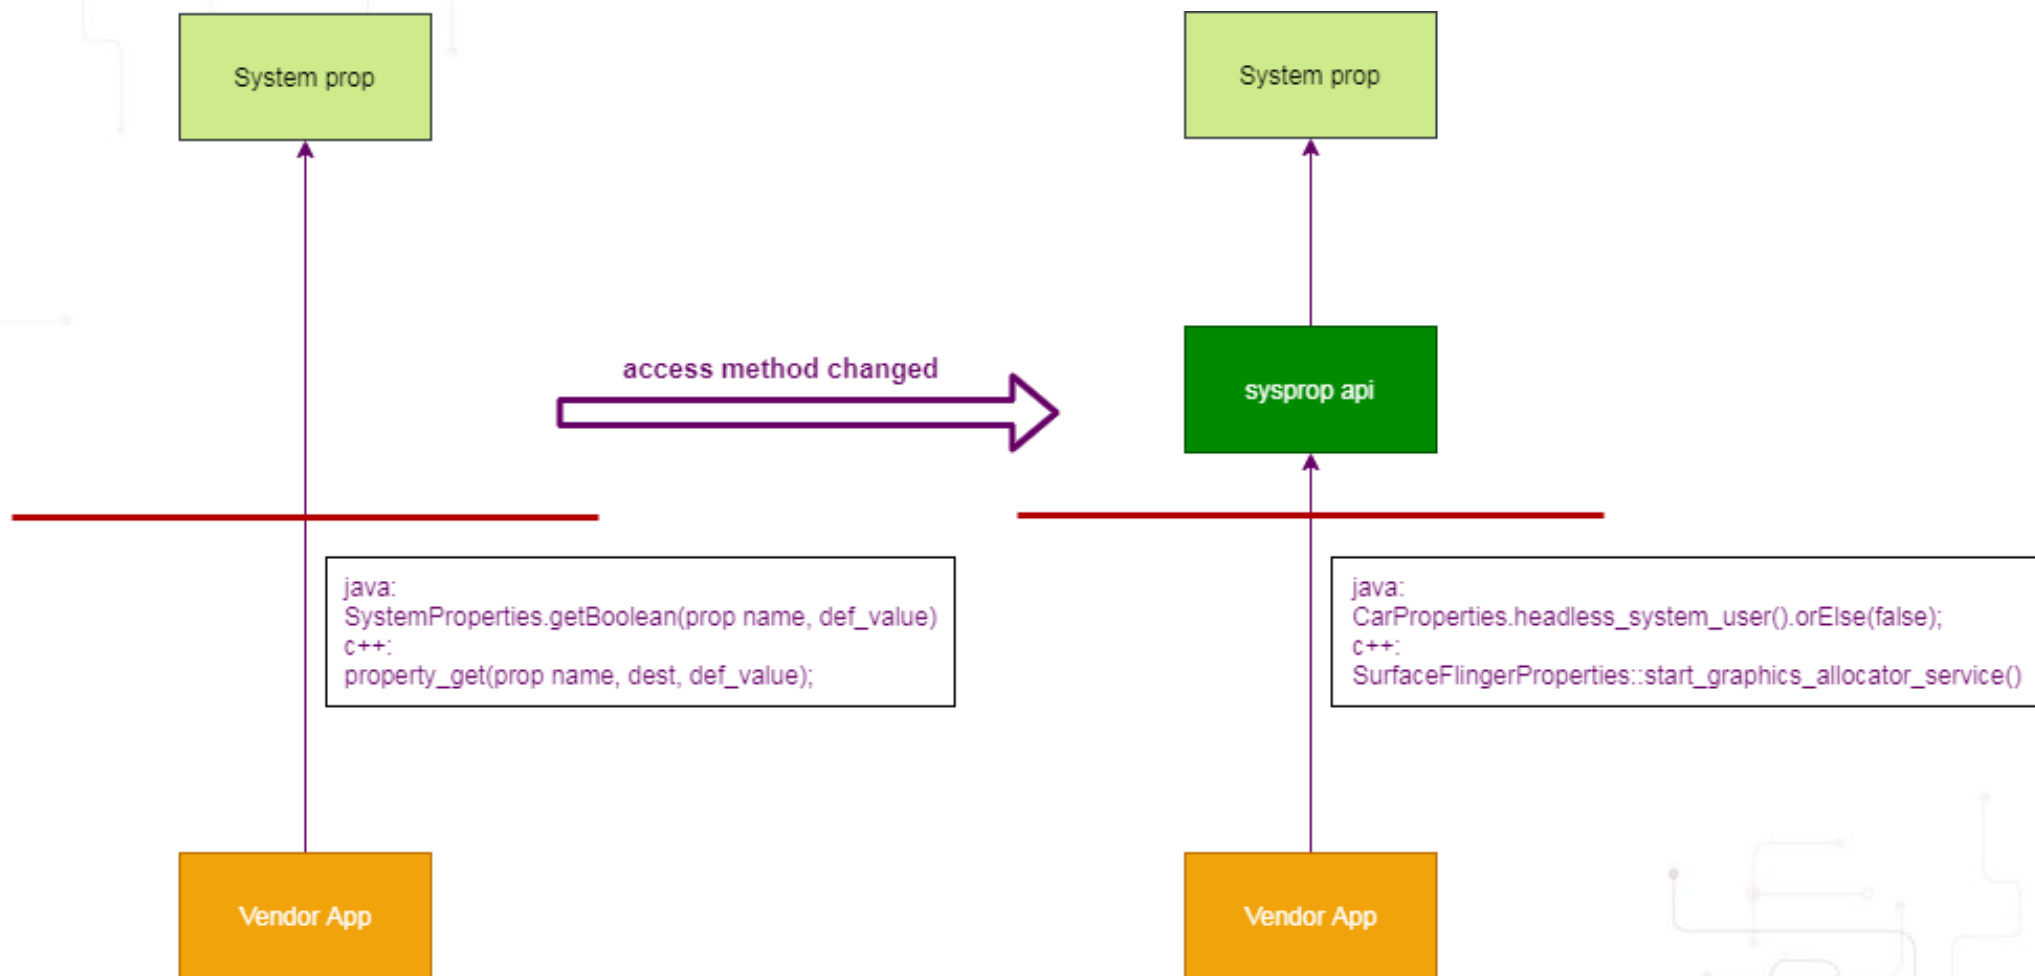

```
import android.sysprop.CarProperties;  
CarProperties.headless_system_user().orElse(false);
```

- C++

```
#include <sysprop/SurfaceFlingerProperties.sysprop.h>  
SurfaceFlingerProperties::start_graphics_allocator_service()
```

## New access method(2/2)

- Follow sysprop owner restrictions
  - Platform : Every partition can access platform-defined properties
  - Vendor : System can't access vendor's properties
  - Odm : Only vendor can access Odm-defined properties

*For details : frameworks/native/services/surfaceflinger/sysprop/api/system-current.txt*

- Follow sysprop Scope restrictions
  - Internal: Only the owner can access.
  - System: Only bundled modules (not built against SDK or NDK) can access.
  - Public: Everyone can access, except for NDK modules.
- Follow Selinux restrictions

## Write a .sysprop file(1/2)

The sysprop file mainly contains two parts.

- Properties
- Property

For the content of these two parts, Google has given the corresponding filling restrictions.

For details on the .sysprop file,  
see `system/tools/sysprop/sysprop.proto`

```
message Properties {  
  Owner owner = 1; // ( Platform/Vendor/Odm )  
  module string module = 2; // module name  
  repeated Property prop = 3; // Property  
}
```

```
message Property {  
  string api_name = 1;      // api name  
  Type type = 2;           // The type of the prop value  
  Access access = 3;       // Read and write permissions  
  Scope scope = 4;         // the scope of api can use  
  string prop_name = 5;    // prop name  
  string enum_values = 6;  // enum values  
  bool integer_as_bool = 7; //Allow integers to be used as bool  
}
```

## Write a .sysprop file(2/2)

An example of a Sysprop Description file :

owner: Platform

module: "android.sysprop.PlatformProperties"

```
prop {  
    api_name: "date_utc"  
    type: Integer  
    prop_name: "persist.build.date_utc"  
    scope: Internal  
    access: ReadWrite  
}
```

```
prop {  
    api_name: "build_date"  
    type: String  
    prop_name: "ro.build.date"  
    scope: System  
    access: Readonly  
}
```

Define sysprop\_library modules with Sysprop Description files

```
sysprop_library {  
    name: "PlatformProperties",  
    srcs: ["android/sysprop/PlatformProperties.sysprop"],  
    property_owner: "Platform",  
    api_packages: ["android.sysprop"],  
    vendor_available: true  
}
```

## How to use it(1/2)

Just like importing other so, we need to reference this defined sysprop in bp

```
java_library {  
    name: "JavaClient",  
    srcs: ["foo/bar.java"],  
    libs: ["PlatformProperties"],  
}  
  
cc_binary {  
    name: "cc_client",  
    srcs: ["baz.cpp"],  
    shared_libs: ["PlatformProperties"],  
}
```

## How to use it(2/2)

In the above example, you could access defined properties as follows.

Java example :

```
import android.sysprop.PlatformProperties;  
  
static void foo() {  
    Integer dateUtc = PlatformProperties.date_utc().orElse(-1);  
}
```

C++ example :

```
#include <android/sysprop/PlatformProperties.sysprop.h>  
  
using namespace android::sysprop;  
  
void bar() {  
    PlatformProperties::build_date("2019-10-31");  
    std::string build_date = PlatformProperties::build_date().value_or("(unknown)");  
}
```

## Currently implemented

Sysprop as api related code path

- syste/tools/sysprop/ → parse the sysprop file to generate the corresponding api
- system/libsysprop/ → the storage path of the Platform-properties sysprop file
- build/soong/sysprop → build rule
